Framework 8.1

Load Distribution Server

User’s Guide
About Genesys
Alcatel-Lucent's Genesys solutions feature leading software that manages customer interactions over phone, Web, and mobile devices. The Genesys software suite handles customer conversations across multiple channels and resources—self-service, assisted-service, and proactive outreach—fulfilling customer requests and optimizing customer care goals while efficiently using resources. Genesys software directs more than 100 million customer interactions every day for 4000 companies and government agencies in 80 countries. These companies and agencies leverage their entire organization, from the contact center to the back office, while dynamically engaging their customers. Go to www.genesyslab.com for more information.

Each product has its own documentation for online viewing at the Genesys Technical Support website or on the Documentation Library DVD, which is available from Genesys upon request. For more information, contact your sales representative.

Notice
Although reasonable effort is made to ensure that the information in this document is complete and accurate at the time of release, Genesys Telecommunications Laboratories, Inc., cannot assume responsibility for any existing errors. Changes and/or corrections to the information contained in this document may be incorporated in future versions.

Your Responsibility for Your System's Security
You are responsible for the security of your system. Product administration to prevent unauthorized use is your responsibility. Your system administrator should read all documents provided with this product to fully understand the features available that reduce your risk of incurring charges for unlicensed use of Genesys products.

Trademarks
Genesys, the Genesys logo, and T-Server are registered trademarks of Genesys Telecommunications Laboratories, Inc. All other trademarks and trade names referred to in this document are the property of other companies. The Crystal monospace font is used by permission of Software Renovation Corporation, www.SoftwareRenovation.com.

Technical Support from VARs
If you have purchased support from a value-added reseller (VAR), please contact the VAR for technical support.

Technical Support from Genesys
If you have purchased support directly from Genesys, please contact Genesys Technical Support at the regional numbers provided on page 8. For complete contact information and procedures, refer to the Genesys Technical Support Guide.

Ordering and Licensing Information
Complete information on ordering and licensing Genesys products can be found in the Genesys Licensing Guide.

Preface

Welcome to the *Framework 8.1 Load Distribution Server User’s Guide*. This document introduces you to the concepts, terminology, and procedures relevant to Load Distribution Server (LDS).

This document is valid only for the 8.1 release of this product.

**Note:** For versions of this document created for other releases of this product, visit the Genesys Technical Support website, or request the Documentation Library DVD, which you can order by e-mail from Genesys Order Management at orderman@genesyslab.com.

This preface contains the following sections:
- About Load Distribution Server, page 7
- Intended Audience, page 8
- Making Comments on This Document, page 8
- Contacting Genesys Technical Support, page 8
- Document Change History, page 9

For information about related resources and about the conventions that are used in this document, see the supplementary material starting on page 83.

About Load Distribution Server

In brief, you will find the following information in this guide:
- A high-level description of Load Distribution Server (LDS) and its uses
- A description of the distribution modes you can configure for LDS
- Procedures for installing and configuring LDS
- A description of all LDS configuration options
- Additional information about using LDS with Genesys Routing solutions

Configuration guidelines for using LDS with Call Concentrator (CCon), which is part of the Genesys Reporting solution
**Intended Audience**

This document is primarily intended for system administrators in contact centers. It has been written with the assumption that you have a basic understanding of:

- Computer-telephony integration (CTI) concepts, processes, terminology, and applications
- Network design and operation
- Your own network configurations

You should also be familiar with Genesys Framework architecture and functions.

**Making Comments on This Document**

If you especially like or dislike anything about this document, feel free to e-mail your comments to Techpubs.webadmin@genesyslab.com.

You can comment on what you regard as specific errors or omissions, and on the accuracy, organization, subject matter, or completeness of this document. Please limit your comments to the scope of this document only and to the way in which the information is presented. Contact your Genesys Account Representative or Genesys Technical Support if you have suggestions about the product itself.

When you send us comments, you grant Genesys a nonexclusive right to use or distribute your comments in any way it believes appropriate, without incurring any obligation to you.

**Contacting Genesys Technical Support**

If you have purchased support directly from Genesys, contact Genesys Technical Support at the following regional numbers:

<table>
<thead>
<tr>
<th>Region</th>
<th>Telephone</th>
<th>E-Mail</th>
</tr>
</thead>
<tbody>
<tr>
<td>North America and Latin America</td>
<td>+888-369-5555 (toll-free)</td>
<td><a href="mailto:support@genesyslab.com">support@genesyslab.com</a></td>
</tr>
<tr>
<td></td>
<td>+506-674-6767</td>
<td></td>
</tr>
<tr>
<td>Europe, Middle East, and Africa</td>
<td>+44-(0)-1276-45-7002</td>
<td><a href="mailto:support@genesyslab.co.uk">support@genesyslab.co.uk</a></td>
</tr>
</tbody>
</table>

Before contacting technical support, refer to the [Genesys Technical Support Guide](#) for complete contact information and procedures.
This is the first release of the Framework 8.1 Load Distribution Server User's Guide. In the future, this section will list topics that are new or that have changed significantly since the first release of this document.
Chapter 1

Overview

This chapter describes four of the five different LDS distribution modes. A fifth mode (*Weighted Round Robin* mode) is described in Chapter 2, “Weighted Round Robin (WRR) Mode,” on page 23. This chapter contains the following topics:

- Concepts, page 11
- Load Distribution Mode, page 13
- TProxy Mode, page 14
- Broadcast Mode, page 17
- Single T-Server LDS Mode, page 18
- New for LDS in Release 8.1, page 20

Concepts

Overview

**Purpose**
LDS is designed to increase system performance in contact center environments with high call volumes. LDS enables load sharing in situations where the total traffic of a large installation exceeds the capacity of individual Receivers. Using LDS with multiple Receivers also increases redundancy in a configuration.

**Terminology**
LDS mediates between _Senders_ and _Receivers_.

A Sender is a T-Server. Any premise or network T-Server can be a Sender.

A Receiver is a T-Server client.

**Smart Distribution of Events**
LDS divides the traffic into manageable portions and distributes it among Receivers by using *smart distribution* of T-Server events (*T-events*). Smart distribution means that LDS correctly identifies all T-events related to a given interaction and passes them on to the appropriate Receiver(s).
At startup, LDS connects to all T-Servers for which it is configured, without waiting for Receiver connections. If it cannot establish a connection at that time with a T-Server at startup, LDS repeats the connection attempt after a Receiver connects to it. LDS stays connected to the T-Servers as long as it is running, but it unregisters from all DNs after the last Receiver disconnects from it.

From the T-Server’s perspective, the type of Receiver is unimportant. The Receiver type that an LDS instance supports is dynamically defined during runtime by the first Receiver to succeed in connecting to LDS. If you need to configure LDS for different Receiver types within the same system, you must use separate instances of LDS for each Receiver type.

**Note:** The type of client application that can be a Receiver differs according to the LDS mode of operation.

You can use LDS in any of the following four distribution modes:

- Load Distribution mode
- TProxy mode
- Broadcast mode
- Single T-Server LDS mode

These modes are described in the remainder of this chapter. More detailed information on specific configurations and usages can be found in later chapters of this document.

You can configure an LDS with application type:

- `LoadDistributionServer`
- `T-Server`

Prior to release 7.0, LDS could operate only in a multi-T-Server configuration. In this configuration and in normal Load Distribution mode, LDS connects to multiple T-Servers to broker messages to multiple Receivers (see Chapter 6, “LDS Support (Load Distribution Mode) of Routing,” on page 33 for an illustration of how this mode operates with the Universal Routing Server (URS) routing client).

From release 7.0 onward, LDS can also operate in a single–T-Server configuration using the functionalities described in this chapter.

You can use the proxy functions described in this chapter only in a single–T-Server environment where an LDS is configured with application type T-Server.
Resulting Distribution Modes

Configuration option `distribute-mode` specifies the default distribution mode of LDS.

As a result of the two application types, and the ability to use LDS in a single–T-Server environment, three distribution modes are available, as shown in Table 1 on page 13.

Table 1: LDS Distribution Modes

<table>
<thead>
<tr>
<th>LDS with Application Type...</th>
<th>Distribution Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>distribute-mode = load</code></td>
<td><code>distribute-mode = auto</code></td>
</tr>
<tr>
<td><code>distribute-mode = proxy</code></td>
<td></td>
</tr>
<tr>
<td>Load Distribution Server</td>
<td>Load Distribution</td>
</tr>
<tr>
<td>T-Server (multiple T-Servers configured in Connections tab)</td>
<td>Load Distribution</td>
</tr>
<tr>
<td>T-Server (single T-Server configured in Connections tab)</td>
<td>Single T-Server LDS</td>
</tr>
</tbody>
</table>

Warning! Please keep in mind that TProxy mode is not compatible with the normal Load Distribution mode. You cannot mix these modes without breaking the load distribution model.

Load Distribution Mode

**Concept**

In Load Distribution mode, LDS distributes requests (balances the load) among the Receivers by using smart distribution of T-events. Smart distribution means that LDS correctly identifies all T-events related to a given interaction and passes them on to the appropriate Receiver(s). Multiple–T-Server configurations can include any combination of premise and network T-Servers.

**Supported Receiver Type**

In Load Distribution mode, LDS supports only the following Receivers:

- URS release 6.5 and later
- CCon, release 6.1.001.12 and later
Chapter 1: Overview

Illustration

Figure 1: LDS in Load Distribution Mode

See Chapter 6, for samples of LDS configurations with Genesys Routing solutions.

Configuration

To configure LDS to operate in Load Distribution mode:

1. In Configuration Manager, create an Application object of type LoadDistributionServer using the LDS_Server_810 application template.
2. Install LDS, choosing Load Distribution mode during the installation procedure.
3. On the Connections tab of the new application, add a connection to each T-Server in the configuration.
4. On the Options tab, set the value of LDS configuration option distribute-mode to load.
5. Configure Receiver connections to point to the new LDS application.

Note: Configuration of the lds-query-dn extension on the switch is mandatory. Configure this setting in the query-dn parameter option on the LDS application to avoid SIP Server (and any other T-Server) EventError messages.

TProxy Mode

Concept

Used in TProxy mode with a single T-Server, LDS reduces the amount of data transmitted over a WAN between remote T-Servers and T-Server clients in a central site. Instead of sending the same events multiple times—one for every client—T-Server sends the events a single time to a central LDS, which then
distributes this event to all clients on the central site that are registered for a particular DN.

TProxy mode has the potential to reduce the volume of data carried over the WAN between T-Server and LDS to \( \frac{1}{N} \) of the volume of data carried over the WAN when clients connect directly to T-Server. This can lead to a substantial cost reduction for the customer in environments where costs are based on number of bytes transmitted.

**Supported Receiver Types**

When LDS is in TProxy mode, Receivers can be of any type and combination of types, provided that they are T-Library compliant. There are limitations to this, however. *For example, ICON is currently not supported in the 8.1.0 release of LDS.*

**Illustration**

Figure 2 illustrates how LDS in TProxy mode distributes TEvent 1. TEvent 1 is carried only once over the WAN before being distributed to all clients registered for the relevant DN. Redundant T-Server and LDS configurations are shown in red.

![Figure 2: LDS in TProxy Mode](image)

**Configuration**

To configure LDS to operate in TProxy mode:

1. In Configuration Manager, create an Application object of type T-Server using the TProxy_Server_810 application template.
2. Install LDS, choosing TProxy mode during the installation procedure.
3. On the Connections tab of the new application, add a connection to a single T-Server.
4. On the Switch tab, add the same switch as is configured for the T-Server you added in Step 3.

5. On the Options tab, set the value of LDS configuration option distribute-mode to either auto or proxy.

6. Configure client connections to point to the new LDS application.

**Note:** From release 7.1, LDS configured in TProxy mode can control both active and passive Receivers simultaneously.

**Note:** Configuration of the lds-query-dn extension on the switch is mandatory. Configure this setting in the query-dn parameter option on the LDS application to avoid SIP Server (and any other T-Server) EventError messages.

### Tiered TProxy Mode

In this section the term TProxy is used to describe an LDS configured in TProxy mode. So a client of such an LDS is a TProxy client, and so on.

Prior to release 7.1, the design of TProxy mode assumed either a TProxy directly connected to T-Server(s), or a TProxy-aware client that was able to access T-Server’s switch configuration by using information from the LDS connection.

From release 7.1, you can create tiered configurations of TProxies, in which one TProxy can be a client of another TProxy. In this structure, a TProxy client can reach switch configuration details at the end of a chain of TProxies (or at any point within the chain where application type T-Server is found).

Such tiered configurations can be used to reduce the amount of network traffic flowing over the WAN between remote and central sites.

### Example Configurations

Figure 3 on page 17 shows how tiered TProxies can be configured in different environments.
Broadcast Mode

**Concept**

In broadcast mode, LDS broadcasts events to any client that requests them. Only special T-Library clients which provide additional information in the connection request can work with LDS in broadcast mode. At the time of this writing, only CCon, URS, and custom applications can connect in this mode.

LDS distributes events to clients accordingly to their subscription (registration on DN for DN based events, registration on call monitored events for call monitoring events, and so on).

**Supported Receiver Types**

In broadcast mode, LDS currently supports the following Receivers:

- URS release 6.5 and later
- CCon, release 6.1.001.12 and later
Illustration

Figure 4 on page 18 illustrates how broadcast mode operates. Redundant T-Server and LDS configurations are shown in red.

Figure 4: LDS in Broadcast Mode

Configuration

To configure LDS to operate in broadcast mode:

1. In Configuration Manager, create an Application object of type LoadDistributionServer using the LDS_Server_810 application template.
2. Install LDS, choosing Load Distribution mode during the installation procedure.
3. On the Connections tab of the new application, configure the relevant connections to T-Servers.
4. On the Options tab of each instance of LDS, set the value of LDS configuration option distribute-mode to proxy.
5. Configure Receiver connections to point to the new LDS application.

Single T-Server LDS Mode

Concept

When LDS is used in this mode, any Receiver can connect to LDS without modification, provided that LDS connects to only a single T-Server.

In earlier versions of LDS that do not support this mode of operation, you must modify Receivers to enable them to connect to multiple T-Servers—when connecting to LDS, the Receiver has to specify which T-Server it wants LDS to
connect to. When LDS connects to only one T-Server, you do not have to modify the Receiver.

**Supported Receiver Types**

With LDS in **Single T-Server LDS** mode, Receivers can be of any type, but must all be of the same type. If Receivers of different types are configured, load distribution becomes meaningless.

**Illustration**

Figure 5 illustrates how this mode operates.

---

**Figure 5: LDS in Single T-Server LDS Mode**

Redundant T-Server and LDS configurations are shown in red.

**Configuration**

To configure LDS to operate in **Single T-Server LDS** mode, follow the steps below.

1. In Configuration Manager, create an Application object of type **T-Server** using the **TProxy_Server_810** application template.

2. Install LDS, choosing **TProxy** mode during the installation procedure.

3. On the **Connections** tab of the new application, add a connection to a single T-Server.

4. On the **Switch** tab, add the same switch as is configured for the T-Server you added in Step 3.

5. On the **Options** tab, set the value of LDS configuration option **distribute-mode** to **load**.

6. Configure Receiver connections to point to the new LDS application.
New for LDS in Release 8.1

This section gives summary details of new features in release 8.1.

- **Support for new operating systems and platforms:**
  - Microsoft Windows Server versions Windows 2008 64-bit
  - Red Hat Linux version 5.0 64-bit
  - IBM AIX version 7.1 64-bit
  - HP-UX IPF version 11i v3 Integrity Native
  - VMware vSphere 4 Hypervisor

- **Support for common component features:**
  - Accesso FLEXNet Publisher version 11.9
  - TCP/IP-v6. For more information, refer to the *Framework 8.1 Deployment Guide*.
  - LDS no longer connects to applications that have disabled status in the configuration environment.
  - The default value of the `background-processing` configuration option has been changed to `true`. See “background-processing” on page 46 for details.

- **Support for the Unresponsive Process Detection feature.** The following configuration options enable this feature:
  - “heartbeat-period” on page 79.
  - “hangup-restart” on page 80.
  For more information, refer to the *Framework 8.0 Management Layer User's Guide*.

- **Support for enhanced logging capability.** The maximum number of log files to be stored using the `expire` configuration option is now 1000. See “expire” on page 63.

- **Support for an alarm for expired requests in STD log mode:** If any requests have expired based on the option `rq-expire-timeout`, STD log messages are written to the log file allowing the customer to generate an alarm.

- **Support for:**
  - **Genesys Administrator (GA).** LDS can be installed and configured using GA.
  - **Sender Link Bandwidth Monitoring.** LDS reports the number of incoming and outgoing messages on all sender links within the time interval specified by the configuration option `load-report-interval`, and reports this using a dedicated LMS message (see “Log Messages” on page 58).
  - **Sender Link Bandwidth Alarm Notification.** LDS can notify the Genesys Management Layer when set limits are exceeded by setting an alarm threshold value as a percentage of maximum throughput. The
value in the configuration option `use-link-bandwidth` represents 100% of bandwidth. High and low watermarks are specified in the options `link-alarm-high` and `link-alarm-low` as a percentage of the highest bandwidth.

- **Enhanced support of T-Server HA failover.** LDS now sends `EventPrimaryChanged` upon a T-Server role change even when the LDS role did not change.

- **Bulk request pacing.** LDS paces requests that were sent to the Sender on behalf of initializing clients, and applies the limit that is set in the configuration option `max-outstanding` for the following requests: `RequestRegisterAddress`, `RequestQueryAddress`, `RequestQueryCall`. The default value of the `background-processing` configuration option has been changed to `true` to accommodate this.
Chapter 2

Weighted Round Robin (WRR) Mode

This chapter provides information about the fifth of the five distribution modes, Weighted Round Robin (WRR) mode. See Chapter 1, “Overview,” on page 11 for details of the other four.

This chapter includes the following sections:

- Concept, page 23
- Configuration Options, page 24

Concept

Weighted Round Robin (WRR) mode is a variant of the standard Load Distribution mode that is achieved by configuring the Receiver application as described in this chapter. With WRR mode, you can alter the loading profile of an individual Receiver (or group of Receivers). So, for a given set of three Receivers, you can configure them to receive, for example, 50 per cent, 30 per cent and 20 per cent of the transactions, or any other proportion depending on your environment.

Receivers can also be grouped, and the loading profile can be set for a group.
Configuration Options

Set the two configuration options in this section in the LDS section of the relevant Receiver application. The section name within the Receiver application must be LDS.

Set the Receiver weighting using the configuration option `loading-coefficient` (see “loading-coefficient” on page 56).

Use the `group-id` option to group a set of Receivers together (see “group-id” on page 55). LDS treats such a group as a single Receiver.
Chapter 3  

Installation

This chapter describes how to install LDS in UNIX/Linux and Microsoft Windows environments. It contains one section:

- Installing LDS, page 25

Installing LDS

This section describes the installation of LDS on UNIX/Linux and Windows.

### Installing on UNIX/Linux

1. On the product CD, locate the appropriate shell script.
2. Run the script from the command prompt by typing `sh` followed by the file name.
3. When prompted, specify the Host Name of the computer on which to install LDS.
4. When prompted, specify the mode of LDS operation (TProxy or LoadDistribution).
5. When prompted, specify the following:
   - Host Name of the computer on which Configuration Server is running.
   - Port that client applications use to connect to Configuration Server.
   - User Name used to log in to the Configuration Layer.
   - Password used to log in to the Configuration Layer.
6. Depending on the mode selected in Step 4, installation displays a list of LDS applications of the relevant type configured for this host. Enter the number of the LDS application that you want to install.
7. Specify the full path of the destination directory into which you want to install LDS.
8. If asked, choose to install either the 32-bit or the 64-bit version, depending on your environment.
Chapter 3: Installation

Installing LDS

9. When prompted, specify the path to a valid license file.

As soon as the installation process is finished, a message appears announcing that the installation was successful. The process places LDS in the directory specified in Step 7.

Installing on Windows

1. From the product CD, locate and double-click the appropriate Setup.exe to start the installation.

2. When prompted, specify the mode of LDS operation (TProxy or LoadDistribution).

3. When prompted, specify the Host and Port of Configuration Server. Accept ITCUtility as the name of the Installation Configuration Utility application.

4. When prompted, specify the User Name and the Password used to log in to the Configuration Layer.

5. Confirm the Host Name of the computer on which to install LDS.

6. Depending on the mode selected in Step 2, installation displays a list of applications of the relevant type configured for this host. From the list, select the LDS application to install.

7. Specify the full path of the directory into which to install LDS.

8. Specify the Program Folder to which you want LDS added.

9. When prompted, specify the path to a valid license file.

10. Decide whether you want to install LDS as a Windows service. For more information, see the Framework 8.1 Deployment Guide.

11. When icons for LDS appear, click Finish to complete the installation.

**Note:** LDS supports Configuration Server backup and Configuration Server proxy configurations.
Chapter 4

Starting and Stopping LDS

This chapter describes how to start and stop LDS. It contains the following topics:

- Starting LDS, page 27
- Stopping LDS, page 28

Starting LDS

Ensure that DB Server and Configuration Server are running. If you are using the Management Layer, ensure that all of its components are running, including Solution Control Interface. For instructions on starting and stopping LDS via the Management Layer, see Solution Control Interface Help in the Genesys Framework 8.1 documentation.

Command-Line Parameters

You must specify command-line parameters (also called command-line arguments) to operate LDS, whether you are operating it manually or with the Management Layer. In manual operation, you either enter parameters directly on a command line or invoke them from a batch file, which is invoked in turn either directly on a command line or via a shortcut on the Windows Start menu. With the Management Layer, you specify the parameters on the Start Info tab (in the Command Line Arguments field) of the LDS Properties window.

This section lists the required command-line parameters. See also the Framework 8.1 Deployment Guide.

Note: The first command-line parameter is always the name of the executable application file. On Windows, it is best to add the extension .exe to the executable file’s name. For example, use LDServer on UNIX/Linux and use LDServer.exe on Windows.

These are the required command-line parameters:

- host <confighost> Represents the host running Configuration Server
-port <configport> Represents the port used by Configuration Server
-app <appname> Represents the name of the application as configured in Configuration Manager
-l <license_file> Represents either of:

The full path to, and the exact name of, the license file. For example, -l /opt/mlink/license/license.dat.

The host name and port of the license server, as specified in the SERVER line of the license file, in the format port@host. For example, -l 7260@ABCserver.

### Stopping LDS

You can stop LDS from the Management Layer, or you can use any of the following manual procedures:

- Use the Ctrl + C command in the component’s console window (on both Windows and UNIX/Linux).
- Use the End Task button in the Windows Task Manager.
- Use the kill <processnumber> command on UNIX/Linux.
Chapter 5

High-Availability (HA) Configuration

This chapter describes high-availability (HA) modes for LDS and Receivers. It contains the following these sections:

- LDS Backup Modes, page 29
- Dynamic HA Model, page 30
- Receiver Backup Modes, page 32

LDS Backup Modes

**Note:** Genesys recommends that LDS pairs used in HA configurations have identical configurations.

LDS supports both warm-standby and hot-standby configurations.

**Warm Standby**

In LDS warm standby mode:

- Both the primary and backup LDSs are connected to all T-Servers using identical configurations.
- The primary LDS accepts Receiver connections and registers to T-Servers for events.
- The backup LDS does not accept Receiver connections and does not register for T-Server events.
- The ha-sync-level configuration option is ignored.
Hot Standby

In LDS hot standby mode:

- Both the primary and backup LDSs (ideally with identical configurations) are connected to all T-Servers.
- From LDS release 6.5.3 onward, the primary and backup LDS can start successfully with different values set in configuration option `ha-sync-level`. When both LDSs are started, the backup LDS adopts the value set for the primary LDS.
- Both the primary and backup LDSs accept Receiver connections and registration requests for T-Server events.
- The primary LDS registers to T-Servers to receive events according to Receiver requests. The backup LDS registers for events in the same way as the primary, but it also asks T-Server to mask events in a way that corresponds to the value set for configuration option `ha-sync-level`. See “Dynamic HA Model” on page 30.
- Only the primary LDS passes events to Receivers and returns responses to T-Servers.
- Both the primary and backup LDSs synchronize transaction context in real time.
- To prevent network overloading, primary and backup LDSs are not synchronized at startup.
- The HA LDS Application Programming Interface (API) enables Receivers to connect to the primary and standby LDSs simultaneously. Registration requests go to both LDSs, and transparently to Receivers. Failover to the backup LDS also occurs transparently.

The standby mode for LDS can be different from the standby mode of T-Servers and of Receivers, and different T-Servers can have different standby modes.

**Note:** From release 6.5.3 onwards, where there is more than one LDS, each instance of LDS starts by default in **Backup** mode, and Management Layer must switch one instance to **Primary** mode.

Dynamic HA Model

Message-Synchronization Queue

From LDS release 6.5.3 onward, a Message-Synchronization Queue feature has been implemented to provide uninterrupted event flow from LDS to Receivers after LDS switchover. The queue enables the backup LDS to track
messages that the primary LDS has already sent. After a switchover, the new primary LDS resumes message distribution from the same point in the message queue at which the old primary LDS had stopped.

Changes to Redundancy Types

Table 2 shows how LDS reacts to dynamic changes to its redundancy type.

Table 2: Effect of Dynamic Changes to LDS Redundancy Types

<table>
<thead>
<tr>
<th>Redundancy Type Changed To...</th>
<th>Not Specified</th>
<th>Warm</th>
<th>Hot</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not specified</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Changes to HA Synchronization Level

Table 3 shows the effects of dynamic changes to the value of configuration option ha-sync-level.

Note: These changes apply only to LDS in hot standby mode.
Receiver Backup Modes

LDS supports backup configurations for Receivers in hot standby mode and for CCon in parallel mode.

Chapter 6

LDS Support (Load Distribution Mode) of Routing

Note: The information in this chapter applies only to LDS in Load Distribution mode. See Chapter 1, “Overview,” on page 11 for a description of this mode.

This chapter provides information on LDS support of Genesys Routing solutions (including Enterprise Routing and Network Routing). It contains the following sections:

- LDS and Routing, page 33
- System Configuration and LDS, page 35
- URS and Backup LDS, page 39
- Additional Information for LDS with URS, page 40

The sections in this chapter explain:

- Routing (including high-availability routing) with LDS.
- The architecture supported by routing components, such as Universal Routing Server (URS) and Interaction Routing Designer (IRD).
- Application redundancy achieved by using LDS.
- Resource registration.
- Agent reservation features with LDS.

LDS and Routing

Use of LDS with Genesys Routing solutions provides a simple, scalable way to improve throughput by combining the processing power of multiple instances.
of URS. The URS instances can run either on single-hardware platforms with multiple processors or on multiple-hardware platforms.

LDS Support of High-Availability Routing

The main reasons for using load distribution with Genesys Routing solutions in contact centers are:

- To meet customer requirements for several hundred interactions per second.
- To increase event throughput of a single URS process, which cannot be increased sufficiently by a hardware upgrade.
- To compensate for the decrease of single-URS throughput caused by complex routing-strategy requirements.
- To provide load distribution that is superior to multithreading, which is complex and does not solve all load distribution needs.
- To increase performance at a cost lower than that of a hardware upgrade.

For information on high-availability options for Enterprise Routing and Network Routing, see the *Universal Routing 8.1 Deployment Guide*.

LDS and Routing Components

LDS and URS

URS performs the following tasks:

- Executes the rules specified within a strategy created in IRD.
- Creates a list of destinations or targets based on the strategy.
- Uses Stat Server statistics to determine the most appropriate target.
- Instructs T-Server where to route an interaction

URS connects to LDS for every T-Server in the LDS Connections list.

Each URS operates independently from other URSs. URS can operate when its Connections list contains connections to both LDS and T-Servers and it can have more than one LDS in its Connections list.

When disconnecting from LDS, URS attempts to connect to a backup LDS (if one has been configured), not to a backup T-Server.

LDS and IRD

IRD is a user interface for creating, editing, loading, and monitoring routing strategies. IRD communicates with URS through Configuration Server. Through a Message Server, IRD also receives from URS real-time routing information about interactions, server status, and Routing Points.
In a non-LDS environment, a strategy is loaded on a Routing Point in only one URS, even if there are multiple URSs monitoring the same Routing Point. However, to ensure consistent routing results in an LDS environment, every URS that is connected to the same LDS and is monitoring the same Routing Point must have the same strategy loaded for that Routing Point.

For information about using IRD, see *Interaction Routing Designer 8.1 Help*.

### Using LDS in Routing Solutions

You can use LDS in Routing solutions to distribute requests among primary URSs and to combine the processing power of URSs to increase total throughput.

In configurations with multiple URSs, LDS distributes interactions among the URSs. This reduces the probability of a URS failure because of decreased processing on any single instance of URS. (For more information on load distribution, see “URS as a Client to LDS”.)

When using LDS, you can achieve redundancy in a configuration with any number of single instances of URS with no dedicated backup URS. In this configuration, when one URS fails, LDS redirects new routing requests to the remaining URS(s). After Management Layer restarts the failed URS, LDS resumes load distribution to all servers.

Redundant configurations using LDS with multiple instances of URS offer a way to scale up Routing solutions when interaction volume exceeds the capabilities of the existing hardware platform.

For more information on redundancy using LDS, see “Scalability for LDS and URS Pairs” on page 38.

### System Configuration and LDS

This section describes some possible ways of configuring LDS with Routing solutions.

**URS as a Client to LDS**

For load distribution in configurations with URS as a client to LDS, connections between T-Server, LDS, and URS occur in the following ways:

- One T-Server to one LDS to multiple URSs
- Multiple T-Servers to one LDS to \( n \) URSs, where \( n \) refers to the number of single instances of URS required to meet the specified load
- Multiple T-Servers to multiple LDSs to multiple URSs
One T-Server, One LDS, and Multiple URSs

Use a configuration with one T-Server to one LDS to multiple URSs when the transaction rate (interactions/second) on the switch/T-Server pair is higher than a single instance of URS can handle. LDS will distribute routing requests (balance the load) among URSs. You can put one or multiple instances of URS on the same computer with multiple processors, or you can distribute URSs on several computers when the contact center’s call volume requires additional processing power.

Multiple T-Servers, One LDS, and Multiple URSs

You can also connect multiple T-Servers to one LDS and multiple URSs to meet the specified load.

Figure 6 illustrates a configuration with LDS at the center of message distribution from multiple T-Servers to multiple URSs.

![Diagram](https://via.placeholder.com/150)

Figure 6: Multiple T-Servers to LDS to Multiple URSs

LDS distributes routing requests (balances the load) among the URSs. The multiple T-Servers can be either premise or network T-Servers.

You can also configure an environment using LDS and an \(n + 1\) URS redundancy configuration without using a backup URS. (Here, \(n\) refers to the number of URSs required to meet the specified load.) When one URS shuts down, LDS redirects new routing requests to the remaining servers until Management Layer restarts the URS that shut down.

This form of redundancy (an \(n + 1\) URS redundancy configuration) is most likely used in configurations with two or more primary URSs performing load balancing without LDS. However, LDS offers a growth path for an enterprise to add routing services when interaction volume increases beyond the capabilities of the existing hardware and software.
**Note:** Because detection and notification of URS failure are communicated through network messaging, you must configure network bandwidths to ensure that no delay occurs between SCS (Solution Control Server), URS, and LDS.

URS can receive and process messages from multiple T-Servers (including T-Server for PBX and Network T-Server) of any media type through the same LDS.

You do not have to install instances of LDS and URS on the same computer. However, you can strategically position LDS and multiple URSs on the same computer to optimize network traffic.

**Multiple T-Servers, LDSs, and URSs**

You can connect a URS to two different LDSs of the same type. This configuration might be necessary when the transaction rate of a single LDS exceeds its capacity; for example, if one LDS handles the transaction load for multiple T-Servers.

Figure 7 illustrates a configuration with multiple T-Servers dividing the transaction load between two LDSs and distributing transactions to multiple URSs. In this figure, URS 3 is also connected to two different LDSs of the same type.

![Figure 7: Multiple T-Servers to Multiple LDSs to Multiple URSs](image)

LDS distributes routing requests according to the routing registration of URS. For information on this topic, see “Additional Information for LDS with URS” on page 40.

**Note:** Because LDS 1 and LDS 2 are not synchronized, there is no guarantee that the same router gets the call after a transfer. This may affect Inter Server Call Control (ISCC).
For information on a phased approach to introducing LDS into an existing architecture, see the *Universal Routing 8.1 Deployment Guide*.

**LDS and Network Routing**

You can add a new URS and LDS to an existing infrastructure to handle extra call volume and to provide scalability when the network’s interaction volume increases beyond the capability of the existing infrastructure. Figure 8 illustrates the addition of a new URS and LDS to a Network Routing solution.

**Scalability for LDS and URS Pairs**

In Figure 9 on page 39, calls are distributed to \(2n\) active servers, each handling approximately a \(1/n\) share of the load. Thus, the proportion of calls that cannot be routed when one server becomes unavailable is \(<= 1/(n-1)\).

The connection between the hot-standby URS and its dependent servers is fully established. When a primary URS shuts down, new routing requests continue to be directed to the hot-standby URS in the pair. After the hot-standby URS becomes the primary URS, it replays the strategy for the pending interactions waiting in the Routing Point.
You can also configure LDS in primary and backup standby pairs. Only the primary LDS accepts connections from URS and registers for T-Server(s).

**Backup LDS in Warm Standby**

When a primary LDS shuts down, Management Layer notifies URS to reconnect to the backup LDS when the LDS failover process is complete. Because a primary and backup LDS pair in warm standby mode are not synchronized, interactions in progress during failover are not recoverable. If there is a breakdown in communications between T-Server and URS during the failover period, the switch might default-route interactions.

**Note:** The fact that URS cannot route interactions in this scenario does not mean that they are irrecoverable. It means that URS cannot take control of these interactions or attempt to route them until after failover is complete.

For more information, see “High-Availability (HA) Configuration” on page 29.
**Backup LDS in Hot Standby**

You can also configure a primary and backup LDS pair in hot standby mode. Primary and hot-standby LDSs accept connections from URS and have connections to T-Server(s). However, only the primary LDS distributes events from T-Server(s).

Because primary and hot-standby LDSs are synchronized in a transaction context, T-Server events that the primary LDS submits are replayed by the hot-standby LDS after failover is complete. This means that no potential interactions are lost during the failover period.

See also “ha-sync-level” on page 48 and “Dynamic HA Model” on page 30.

---

**Additional Information for LDS with URS**

After you have configured and installed LDS, you can set up the routing environment. There are no routing-specific options that you need to set up in LDS or URS to enable routing to work with LDS; you have already set up options for LDS. (See page 45.) However, to get the most benefit from LDS, you need to take actions in respect of the following:

- LDS and Receiver type
- Resource registration
- Agent reservation options

**LDS and Receiver Type**

Currently, LDS is type specific. As a result, URS (the Receiver) can connect only to the LDS assigned to URS(s)—URS cannot connect to an LDS in Load Distribution mode that is already serving CCon clients.

LDS determines its type dynamically during runtime from the type of the first successful client connection to LDS; therefore, no explicit option settings are required.

**Resource Registration**

URS registers all Routing Points except those with option event_arrive configured and set to none in the Routing Point or virtual Routing Point properties. (This means that if you have not configured option event_arrive, URS registers for this Routing Point.) If URS is not registered to the specific Routing Point, URS receives no routing requests. Within a given LDS configuration, URS uses this mechanism to register to different Routing Points. *Figure 10* illustrates this scenario.
In Figure 10, URS 2 does not receive routing requests from T-Server 1. You establish this by configuring the Annex tab in the T-Server 1 Application object with a folder bearing the name of the URS 1 application at the individual Routing Point-level or virtual Routing Point-level.

LDS distributes the load (routing requests) according to the registration of Routing Points in URS. Interactions from T-Server 1 are sent only to URS 1. Interactions from T-Server 2 are distributed in Load Distribution mode between URS 1 and URS 2, and interactions from T-Server 3 are distributed only to URS 2. For load distribution of interactions from T-Server 2, the load on URS 1 and URS 2 (from processing interactions of T-Server 1 and T-Server 3) is taken into account.

**Note:** Using LDS does not affect Inter Server Call Control (external) routing functionality related to Routing.

### Agent Reservation Options

Using LDS to achieve redundancy or load distribution always requires two or more URSs to route interactions from multiple T-Servers. In a configuration with LDS, the probability of having two URSs requesting the same routing target is higher. As a result, you must enable the Agent Reservation feature when using LDS.
Four options are related to the Agent Reservation feature at the URS application level (see the *Universal Routing Reference Manual* and the *Universal Routing Deployment Guide* for complete information about how these options function):

- **agent_reservation**
  This option is set at the URS Application level. It instructs URS to send a `reserve agent` request to T-Server and to wait for confirmation from T-Server before routing interactions to an agent.

- **transition_time**
  This option defines the minimum time (in seconds) that URS waits between the moment an interaction is routed to a target such as an agent, a place, or a DN, and any subsequent check for routing to the same target. To avoid repeated routing to the same target, you must set a nonzero value for this option.

- **reservation_pulling_time**
  This option temporarily eliminates the regular 2-second pause cycle for URS to select each routing target. With this option enabled, URS sends a reservation request for another ready agent immediately after a negative response to the preceding request. Enabling this option increases network traffic.

- **treatment_delay_time**
  This option delays treatment if `agent_reservation` is used.

Two options are related to the Agent Reservation feature at the T-Server application level. See the appropriate Deployment Guide for your specific T-Server for more details:

- **reservation_time**
  This option determines the time interval (in milliseconds) to reserve an agent. During that interval the agent cannot be reserved again. Use this option to handle race conditions caused by two or more routing requests for the same target. It does not work for multidirect (for example, direct transfers between agents) or multi-ACD interactions.

- **reject-subsequent-request**
  With value `true`, T-Server rejects subsequent requests for an agent reservation from the same client application for the same `Agent` object. With value `false`, a subsequent request prolongs the current reservation made by the same client application for the same agent.

**Note:** You must set the value of this option to `true` in all T-Servers that are LDS clients.
Chapter 7

LDS Support (Load Distribution Mode) of Call Concentrator

Note: The information in this chapter applies only to LDS in Load Distribution mode.

This chapter provides recommendations on using LDS and Call Concentrator (CCon). It contains:
- Recommended Configuration, page 43

Recommended Configuration

The recommended CCon configuration in an LDS (Load Distribution mode) environment comprises a redundant LDS process that receives T-events from all T-Servers, then distributes them to $N + 1$ CCon processes. (Here, $N$ is the total expected traffic, divided by the traffic expected to be processed by a single CCon).

Additionally, you must set alarms in Management Layer against CCon’s log events that indicate a database problem. It is also desirable to configure these alarms to automatically shut down the Call Concentrator process that reported the related event. Refer to Call Concentrator and Management Layer documentation for full details on how to do this.

This configuration ensures that if any Call Concentrator is closed down in this scenario, LDS automatically redistributes the load among the remaining processes that have enough processing power to handle it. Therefore, only the interactions in progress at the time of failure are affected.
**Note:** Setting the LDS configuration option `no-context-distribution` to value `all` allows Call Concentrator to populate AREC tables for non-call-related data, including custom states. Such data is most likely to be duplicated.
Chapter 8

LDS Configuration Options and Log Messages

This chapter describes the configuration options and log messages specific to LDS. It contains the following sections:

- LDS Section, page 45
- LDS Options Configured in Receivers, page 55
- Changes from Release 7.2 to 8.1, page 56
- Log Messages, page 58

Log options common to all servers are described in the “Common Configuration Options” chapter of this document. Common log messages are described in Genesys 8.1 Combined Log Events Help.

LDS Section

You can find the LDS configuration options in a section called LDS on the Options tab of the Properties window of the LDS Application object. The options in this section are listed in alphabetical order.

**active-context-limit**

Default Value: 1000000

Valid Value: Any integer from 1-1000000

Changes Take Effect: Immediately

Specifies the default maximum number of active transactions that each Receiver can process simultaneously. You can also configure this option per Receiver in the LDS section in the Receiver application. If you do so, that value overrides the default value set in the LDS application properties.
**background-processing**
Default Value: `true`
Valid Values: `true, false`
Changes Take Effect: Immediately

With Background Processing functionality enabled, LDS reads all messages immediately and waits until there are no messages before processing the message queue associated with LDS client requests. LDS reads all connection sockets immediately and places client requests in the input buffer, which prevents LDS clients from disconnecting because of configured timeouts.

When LDS processes client requests from the message queue, requests are processed in the order in which LDS received them.

When set to `false`, LDS processes all requests from one LDS client before proceeding to the requests from another LDS client, and so on.

**background-timeout**
Default Value: `60`
Valid Value: Any integer from `1-1000`
Changes Take Effect: Immediately

With the `background-processing` functionality enabled (option `background-processing` set to `true`), this option limits how long LDS will process requests from a non-empty background queue.

**cleanup-timer**
Default Value: `60`
Valid Value: Any integer from `10-60`
Changes Take Effect: Immediately

Defines (in seconds) how often LDS sends query requests to T-Server to check the status of non-active transactions.

**context-cleanup**
Default Value: `60`
Valid Value: Any integer from `15-11520`
Changes Take Effect: Immediately

Defines the time (in minutes) that LDS waits after the last event is received for an active transaction before querying T-Server to check whether the call still exists.

**context-remove-delay**
Default Value: `5`
Valid Value: Any integer from `5-60`
Changes Take Effect: Immediately
Specifies the interval (in seconds) for which the Connection ID of a call is kept after T-Server reports End-0f-Call. This interval is useful for call distribution in Inter Server Call Control (ISCC).

**count-active-context**
Default Value: false
Valid Values: true, false
Changes Take Effect: Immediately
With value true, LDS counts the total number of active transactions for each Receiver and issues an alarm when the number of transactions defined in the active-context-limit option is reached.

**distribute-mode**
Default Value: auto
Valid Values: auto, load, proxy
- auto With value auto, LDS selects its own mode depending on its actual configuration environment. With LDS configured in Configuration Manager with application type T-Server and one T-Server added on the LDS Connection tab, LDS operates in proxy mode. For all other possible configurations, LDS operates in Load Distribution mode.
- load With value load, LDS is forced into LoadDistribution mode.
- proxy With value proxy, LDS acts as proxy between T-Server and clients
Changes Take Effect: Immediately
Specifies the default distribution mode of LDS.

**Note:** Genesys recommends that you do not make changes without careful preparation, because the effect on client applications of changing between Proxy and LoadDistribution modes could cause unexpected effects.

**enable-safe-handover**
Default Value: false
Valid Values: true, false
Changes Take Effect: Immediately
This option instructs LDS to distribute the last EventRouteRequest for the transaction on the Routing Point to the new Receiver when the last Receiver that served this transaction is disconnected prior to completion of routing
With value true, an EventRouteRequest distributed to the disconnected Receiver will be re-sent to the new one. With value false, the new Receiver will receive the next event for the transaction.
ha-dly-switchover
Default Value: false
Valid Values: true, false
Changes Take Effect: Immediately
Determines whether the backup LDS delays switching into the running state for Management Layer until it has been notified that target synchronization has completed. With value false, the backup LDS switches into running state as soon as the backup link is established.

ha-sync-level
Default Value: 1
Valid Values:
0 The backup LDS does not receive events from T-Server until it becomes primary. Synchronization between primary and backup LDS is performed with each transaction. Genesys advises against using this value in production environments with high call volumes because messages can be lost in failover scenarios.
1 Both primary and backup LDS receive all events from T-Server. Synchronization between primary and backup LDS is performed with each transaction. Using this value increases network traffic.
2 Both the primary and backup LDS receive all events from T-Server. Synchronization between primary and backup LDS is performed with each T-Server event. Using this value increases network traffic as well as the resource usage of LDS.
Changes Take Effect: Immediately
 Defines the level of synchronization between a primary and backup LDS application. Increasing the value of this option reduces the risk of event loss in a switchover/failover scenario, but increases network traffic.

Note: The ha-sync-level option applies to primary/backup LDS Applications in hot standby mode only, and (from release 6.5.3 onward) is automatically adapted to the LDS redundancy level. If you have configured LDS in warm standby mode, this option is ignored. The backup and primary LDS can start with different values set for this option (though Genesys does not recommend this), but the backup LDS automatically adopts the value configured in the primary LDS.

intra-cluster-distribution
Default Value: all
Valid Values: one, all
Changes Take Effect: Immediately
Chapter 8: LDS Configuration Options and Log Messages

LDS Section

Specifies whether to distribute transactions to one Receiver in a cluster (value one), or all Receivers (value all).

If a nominated Receiver in such a configuration fails, LDS distributes subsequent transactions to the next Receiver as per Warm Standby (that is, no synchronization).

**keep-ext-key**

Default Value: No default value

Valid Values: Comma-separated list of extensions

Changes Take Effect: Immediately

Specifies the list of extensions that should be preserved when LDS is removing ConnectionID-related extensions from events EventRegistered and EventAddressInfo.

When the connection ID found in extension “connid-N” is masked for particular Receivers (where N is a positive integer greater than or equal to 0), and all extensions with a prefix of N have not been distributed to them, LDS preserves the key in the format ExtKey-N when ExtKey is listed in this configuration option.

**keep-taction-stat**

Default Value: 5

Valid Value: Any integer from 1-1440

Changes Take Effect: Immediately

Defines the length of time (in minutes) that LDS maintains information about Receiver loading in order to perform even distribution.

**license-file**

Default Value: No default value

Valid Value: Valid path to a valid license file

Changes Take Effect: Immediately if command-line parameter -l is not specified

Specifies the location of the license file from which LDS obtains the license, if the license file location is not specified on startup (using the -l command-line parameter).

**link-alarm-high**

Default Value: 0

Valid Value: Any integer from 0-100

Changes Take Effect: Immediately

Specifies the percentage of the use-link-bandwidth option when LMS message 39570 (MSG ALARM HIGH) is generated. When set to 0, the alarm feature is disabled.
**link-alarm-low**

Default Value: 0
Valid Value: Any integer from 0–100
Changes Take Effect: Immediately

Specifies the percentage of the `use-link-bandwidth` option when LMS message 39571 (MSG ALARM LOW) is generated. When set to 0, the alarm feature is disabled.

**link-by-originator**

Default Value: false
Valid Values: true, false
Changes Take Effect: Immediately

With value true, LDS attempts to link a known in-progress interaction with a new one using ThisDN, OtherDN, or ThirdPartyDN information from the call events when the link cannot be established using PreviousConnID.

**load-report-interval**

Default Value: 15
Valid Value: Any integer from 0–120
Changes Take Effect: Immediately

Specifies (in minutes) how often LDS will output the LMS message 39572 (MSG LOAD INFO). This LMS message contains the number of outgoing and incoming messages across all Sender links during the configured interval.

**max-outstanding**

Default Value: 4
Valid Value: Any integer from 0–2048
Changes Take Effect: Immediately

 Specifies the maximum number of messages of type `RequestRegisterAddress`, `RequestQueryAddress`, and `RequestQueryCall` that can be sent to a single Sender at any given time without being acknowledged.

**max-update-rate**

Default Value: 100 K
Valid Values: See description
Changes Take Effect: Immediately

Defines the settings that manage the HA link load during initial transaction synchronization between the primary and backup LDSs.

- 0: Primary LDS informs backup about the transaction target only when the transaction is either created or became active (that is, a transaction-related event is received).
- Non-0 value: In addition to updates for new and active transactions, the primary LDS will send the specified number of updates for
inactive non-synchronized transactions to the backup LDS per second.

The option is defined using format $x<K|M|G>$ and the following rules apply:

- A value $x$ without a suffix instructs LDS to use that value in bps.
- A value $x$ with suffix $K$ instructs LDS to use that value in kbps.
- A value $x$ with suffix $M$ instructs LDS to use that value in mbps.
- A value $x$ with suffix $G$ instructs LDS to use that value in gbps.

The value defines overall traffic on the backup link. For transaction synchronization, LDS uses available “spare” bandwidth.

**Example**

Primary/backup synchronization for 10 cps (calls per second) and 10 messages per call where `ha-sync-level` = 2 generates around 100 kbps of traffic (without overhead) on an HA link.

**Note:** The option is effective for a primary LDS running in HA Hot-Standby mode.

**msg-duplication**

**Default Value:** 0

**Valid Value:** Any integer from 0-10

**Changes Take Effect:** Immediately

Defines the number of additional Receivers that receive duplicate event messages. With value 0 (zero), only one Receiver receives the event flow for each transaction. With value 1, two Receivers receive the event flow for each transaction, and so on.

This option relates to multiple Receivers in primary mode and does not conflict with HA Receiver mode, in which the same event is sent to two Receivers.

**Warning!** Use extreme caution when changing the value of this option from its default setting of 0 (zero). Setting nonzero values increases availability. Please consult the documentation for your Receiver application to determine whether it supports nonzero values for this option.

**no-context-distribution**

**Default Value:** `first`

**Valid Values:** none, first, all

- **none** Any events that do not have a call context are not distributed to Receivers.
- **first** Events with no call context are distributed to the first Receiver to connect to LDS at startup. If this Receiver is disconnected, LDS selects another Receiver to receive such events.
Events with no call context are broadcast to all connected Receivers that are registered for the device in question.

Changes Take Effect: Immediately

Defines which LDS Receiver or Receivers (none, only the first Receiver, or all Receivers) should receive messages without a call context. Currently this includes all T-Server events without a Connection ID.

**Warning!** If you are using URS version 7.5 or higher and you have more than one URS registering with LDS for same Routing Point, you need to set the value of this option to all to make sure all non-call-related events are sent from LDS to all URSs. Please be aware that this setting will impact performance. Genesys recommends not to use value all if you have Call Concentrator connected to the LDS.

**Note:** With value first, the first Receiver assignment may be changed when the set of Receivers is changed; for example, when a Receiver is dynamically added or deleted.

**query-dn**
Default Value: lds-query-dn
Valid Value: Any character string
Changes Take Effect: Immediately

Specifies the name of the DN that LDS uses to perform queries for calls.

**query-timer**
Default Value: 2
Valid Value: Any integer from 1-60
Changes Take Effect: Immediately

Defines the time (in minutes) between the receipt of the last event for an active transaction and an LDS query to T-Server to check whether the call still exists.

**Note:** The value of query-timer supersedes the value of option context-cleanup because LDS uses a different procedure for querying calls in T-Server releases 6.5.3 and later.

Genesys recommends setting the value of query-timer to half (or less) that of the value set for the context-cleanup option.

**queue-expire-timeout**
Default Value: 600
Valid Values: Any integer from 1-3600
Changes Take Effect: Immediately
Specifies the maximum time, in seconds, that LDS can keep a request queued before deleting it.

**register-guard**

Default Value: 5  
Valid Values: Any integer from 0-30  
Changes Take Effect: Immediately

Defines the timeout (in seconds) between LDS issuing a LinkConnected event (or a consecutive RegisterAddress event) to the client and the beginning of distribution of transactions to this client.

**register-mode**

Default Value: tproxy  
Valid Values: tproxy, tserv  
Changes Take Effect: Immediately

Defines how LDS in TProxy mode will process RequestRegisterAddress when different clients are required to register with different RegisterMode values. Please consult the T-Library SDK Developers Guide for more information on TRegisterMode support in T-Servers.

With value tproxy, LDS will override the RegisterMode received from the client and always use ModeShare when a request is sent to the Sender.

With value tserv, LDS internally emulates the Genesys T-Server handling for RegisterMode.

**Note:** Applicable for LDS in TProxy mode only.

**rq-expire-timeout**

Default Value: 120  
Valid Value: Any integer from 10-600  
Changes Take Effect: Immediately

Instructs LDS to delete a request from the client, as it has not received a response after the specified timeout. LDS sends EventError (Timeout) to the client requester. Depending on the event type, LDS either (1) does not distribute the event, or (2) strips the reference ID from the event if a response eventually arrives.

**server-id**

Default Value: ApplicationDBID  
Valid Values: 0...16383  
Changes Take Effect: Immediately

Specifies the Server ID that LDS uses to generate Connection IDs and other unique identifiers. In a multi-site environment, you must assign each LDS a unique Server ID, in order to avoid confusion in reporting applications and
LDS behavior. Configuration of this option is necessary for Framework environments in which there are two or more instances of the Configuration Database.

**Note:** If you do not specify a value for this option, LDS populates it with the ApplicationDBID as reported by Configuration Server. Each data object in the Configuration Database is assigned a separate DBID that maintains a unique Server ID for each LDS configured in the database.

---

**stat-calc-threshold**

Default Value: 1  
Valid Value: Any integer from 0-100  
Changes Take Effect: Immediately  

Specifies the frequency with which LDS recalculates internal statistics to sort available Receivers according to their loading. Value 1 means LDS recalculates with every transaction; value 10, with every 10 transactions, and so on. The higher the value, the less frequent the recalculation.

---

**strict-backup-name**

Default Value: false  
Valid Values: true, false  
Changes Take Effect: Immediately  

With value true, LDS does not accept clients requests for connection to non-running (or passive) T-Servers. With value false, LDS does accept such requests (pre-7.1 behavior).

---

**tlib-verbose**

Default Value: 0  
Valid Values: 0..2  
Changes Take Effect: Immediately  

Enables T-Library debugging messages in the LDS log.

---

**update-timestamp**

Default Value: false  
Valid Values: true, false  
Changes Take Effect: Immediately  

Defines if LDS uses the current LDS time to update the timestamp attribute in all events sent to Receivers. With value false, all LDS clients receive the T-Server timestamp in events.

**Note:** LDS does not perform any kind of conversion between time zones.
use-link-bandwidth
Default Value: 0
Valid Value: Any integer from 0–999
Changes Take Effect: Immediately
Specifies the number of messages per second throughput to indicate the maximum throughput. When set to 0, this feature is disabled.

use-query-call
Default Value: true
Valid Values: true, false
Changes Take Effect: Immediately
Specifies whether, when working with Senders with no “call-end-support,” LDS uses QueryCall to verify the existence of the call in the Sender (where supported).
With value false, no QueryCall request is made to the Sender.

LDS Options Configured in Receivers
Set the following three configuration options in the LDS section of the relevant Receiver application. The section name within the Receiver application must be LDS.

active-context-limit
Default Value: Value of the active-context-limit option in the LDS application
Valid Value: Any integer from 1–100000
Changes Take Effect: Immediately
Defines the maximum number of active transactions a specific Receiver is able to process simultaneously. This value overrides the value defined by the option active-context-limit in the default section in the LDS application for a specific Receiver.

group-id
Default Value: 0
Valid Value: Any integer from 0–65535
Changes Take Effect: At LDS restart
Specifies whether this Receiver is part of a group. When you configure two or more Receivers with the same value for this option, LDS treats them as a single group and they receive the same event set.
Configure this option with caution. The fact that grouped Receivers receive identical call information has potential impacts on Receiver functionality; for example, duplicated records in Call Concentrator, calls being routed by two different URSs, and so on).
Note: You must ensure that both Receivers in the Configuration Manager primary/backup pair have the same value for the group-id option (if the option is configured). From release 7.1, the Configuration Manager primary/backup setting takes precedence.

loading-coefficient
Default Value: 100
Valid Value: Any integer from 0–100
Changes Take Effect: Immediately
Defines the relative loading coefficient for each specific Receiver for Weighted Round Robin (WRR) mode. For example, a set of three identical Receivers configured with loading coefficients 100, 70, and 30 receive 50 percent, 35 percent and 15 percent, respectively, of the total number of transactions.

If you use the default value (100) for all Receivers (100), you disable WRR and transactions are distributed in Load Distribution mode. If you set any non-default value for any one Receiver (or Receiver group), you enable WRR.

Note: With value 0 (zero), a Receiver is excluded from transaction distribution. However, distribution to this Receiver is still possible, either when no other targets are available (for example, there are no more Receivers, or no more Receivers registered on a specific resource) or when this Receiver is available for non-context distribution.

Changes from Release 7.2 to 8.1
Table 4 on page 57 lists the configuration options that:
• Are new or changed in the 8.1 release of Load Distribution Server
• Have been added or changed since the most recent 7.2 release of this document

If a configuration option has been replaced with another that enables the same functionality, the new option name and its location in this chapter are noted.

Chapter 9

Common Configuration Options

Unless otherwise noted, the common configuration options that this chapter describes are common to all Genesys server applications and applicable to any Framework server component. This chapter includes the following sections:

- Setting Configuration Options, page 61
- Mandatory Options, page 62
- log Section, page 62
- log-extended Section, page 76
- log-filter Section, page 78
- log-filter-data Section, page 78
- security Section, page 79
- sml Section, page 79
- common Section, page 81

Note: Some server applications also support log options that are unique to them. For descriptions of a particular application’s unique log options, refer to the chapter/document about that application.

Setting Configuration Options

Unless specified otherwise, set common configuration options in the Options of the Application object, using one of the following navigation paths:

- In Genesys Administrator—Application object > Options tab > Advanced View (Options)
- In Configuration Manager—Application object > Properties dialog box > Options tab
Warning! Configuration section names, configuration option names, and predefined option values are case-sensitive. Type them in Genesys Administrator or Configuration Manager exactly as they are documented in this chapter.

Mandatory Options

You do not have to configure any common options to start Server applications.

log Section

This section must be called log.

verbose

Default Value: all
Valid Values:

- all: All log events (that is, log events of the Standard, Trace, Interaction, and Debug levels) are generated.
- debug: The same as all.
- trace: Log events of the Trace level and higher (that is, log events of the Standard, Interaction, and Trace levels) are generated, but log events of the Debug level are not generated.
- interaction: Log events of the Interaction level and higher (that is, log events of the Standard and Interaction levels) are generated, but log events of the Trace and Debug levels are not generated.
- standard: Log events of the Standard level are generated, but log events of the Interaction, Trace, and Debug levels are not generated.
- none: No output is produced.

Changes Take Effect: Immediately

Determines whether a log output is created. If it is, specifies the minimum level of log events generated. The log events levels, starting with the highest priority level, are Standard, Interaction, Trace, and Debug. See also “Log Output Options” on page 68.

buffering

Default Value: true
Valid Values:

true Enables buffering.
false Disables buffering.

Changes Take Effect: Immediately

Turns on/off operating system file buffering. The option is applicable only to the stderr and stdout output (see page 68). Setting this option to true increases the output performance.

**Note:** When buffering is enabled, there might be a delay before log messages appear at the console.

### segment

Default Value: false

Valid Values:

false No segmentation is allowed.
<number> KB or <number> MB Sets the maximum segment size, in kilobytes or megabytes.
<number> hr Sets the number of hours for the segment to stay open. The minimum number is 1 hour.

Changes Take Effect: Immediately

Specifies whether there is a segmentation limit for a log file. If there is, sets the mode of measurement, along with the maximum size. If the current log segment exceeds the size set by this option, the file is closed and a new one is created. This option is ignored if log output is not configured to be sent to a log file.

### expire

Default Value: false

Valid Values:

false No expiration; all generated segments are stored.
<number> file or <number> day Sets the maximum number of log files to store or the maximum number of days before log files are deleted. Specify a number from 1–1000.

Changes Take Effect: Immediately

Determines whether log files expire. If they do, sets the measurement for determining when they expire, along with the maximum number of files (segments) or days before the files are removed. This option is ignored if log output is not configured to be sent to a log file.
**Note:** If an option’s value is set incorrectly—out of the range of valid values—it will be automatically reset to 10.

### keep-startup-file

Default Value: `false`

Valid Values:

- `false`: No startup segment of the log is kept.
- `true`: A startup segment of the log is kept. The size of the segment equals the value of the `segment` option.
- `<number> KB`: Sets the maximum size, in kilobytes, for a startup segment of the log.
- `<number> MB`: Sets the maximum size, in megabytes, for a startup segment of the log.

Changes Take Effect: After restart

Specifies whether a startup segment of the log, containing the initial T-Server configuration, is to be kept. If it is, this option can be set to `true` or to a specific size. If set to `true`, the size of the initial segment will be equal to the size of the regular log segment defined by the `segment` option. The value of this option will be ignored if segmentation is turned off (that is, if the `segment` option set to `false`).

**Note:** This option applies only to T-Servers.

### messagefile

Default Value: As specified by a particular application

Valid Values: `<string>.lms` (message file name)

Changes Take Effect: Immediately, if an application cannot find its `*.lms` file at startup

Specifies the file name for application-specific log events. The name must be valid for the operating system on which the application is running. The option value can also contain the absolute path to the application-specific `*.lms` file. Otherwise, an application looks for the file in its working directory.

**Warning!** An application that does not find its `*.lms` file at startup cannot generate application-specific log events and send them to Message Server.
**message-format**

Default Value: `short`

Valid Values:

- **short**: An application uses compressed headers when writing log records in its log file.
- **full**: An application uses complete headers when writing log records in its log file.

Changes Take Effect: Immediately

Specifies the format of log record headers that an application uses when writing logs in the log file. Using compressed log record headers improves application performance and reduces the log file’s size.

With the value set to `short`:

- A header of the log file or the log file segment contains information about the application (such as the application name, application type, host type, and time zone), whereas single log records within the file or segment omit this information.
- A log message priority is abbreviated to `Std`, `Int`, `Trc`, or `Dbg`, for Standard, Interaction, Trace, or Debug messages, respectively.
- The message ID does not contain the prefix `GCTI` or the application type ID.

A log record in the full format looks like this:

```
2002-05-07T18:11:38.196 Standard localhost cfg_dbserver GCTI-00-05060 Application started
```

A log record in the short format looks like this:

```
2002-05-07T18:15:33.952 Std 05060 Application started
```

**Note:** Whether the full or short format is used, time is printed in the format specified by the `time_format` option.

**time_convert**

Default Value: `Local`

Valid Values:

- **local**: The time of log record generation is expressed as a local time, based on the time zone and any seasonal adjustments. Time zone information of the application’s host computer is used.
- **utc**: The time of log record generation is expressed as Coordinated Universal Time (UTC).

Changes Take Effect: Immediately

Specifies the system in which an application calculates the log record time when generating a log file. The time is converted from the time in seconds since the Epoch (00:00:00 UTC, January 1, 1970).
**time_format**
Default Value: `time`
Valid Values:
- `time`: The time string is formatted according to the `HH:MM:SS.sss` (hours, minutes, seconds, and milliseconds) format.
- `locale`: The time string is formatted according to the system’s locale.
- `ISO8601`: The date in the time string is formatted according to the ISO 8601 format. Fractional seconds are given in milliseconds.

Changes Take Effect: Immediately
Specifies how to represent, in a log file, the time when an application generates log records.
A log record’s time field in the ISO 8601 format looks like this:
`2001-07-24T04:58:10.123`

**print-attributes**
Default Value: `false`
Valid Values:
- `true`: Attaches extended attributes, if any exist, to a log event sent to log output.
- `false`: Does not attach extended attributes to a log event sent to log output.

Changes Take Effect: Immediately
Specifies whether the application attaches extended attributes, if any exist, to a log event that it sends to log output. Typically, log events of the Interaction log level and Audit-related log events contain extended attributes. Setting this option to `true` enables audit capabilities, but negatively affects performance. Genesys recommends enabling this option for Solution Control Server and Configuration Server when using audit tracking. For other applications, refer to *Genesys 8.0 Combined Log Events Help* to find out whether an application generates Interaction-level and Audit-related log events; if it does, enable the option only when testing new interaction scenarios.

**check-point**
Default Value: `1`
Valid Values: `0–24`

Changes Take Effect: Immediately
Specifies, in hours, how often the application generates a `check-point` log event, to divide the log into sections of equal time. By default, the application generates this log event every hour. Setting the option to `0` prevents the generation of `check-point` events.
**memory**

Default Value: No default value  
Valid Values: `<string>` (memory file name)  
Changes Take Effect: Immediately  

Specifies the name of the file to which the application regularly prints a snapshot of the memory output, if it is configured to do this (see “Log Output Options” on page 68). The new snapshot overwrites the previously written data. If the application terminates abnormally, this file will contain the latest log messages. Memory output is not recommended for processors with a CPU frequency lower than 600 MHz.

**Note:** If the file specified as the `memory` file is located on a network drive, an application does not create a snapshot file (with the extension `*.memory.log`).

**memory-storage-size**

Default Value: 2 MB  
Valid Values:

- `<number> KB` or `<number> MB`  
  The size of the memory output, in kilobytes.  
  The minimum value is 128 KB.  
  The maximum value is 64 MB.

Changes Take Effect: When memory output is created  

Specifies the buffer size for log output to the memory, if configured. See also “Log Output Options” on page 68.

**spool**

Default Value: The application’s working directory  
Valid Values: `<path>` (the folder, with the full path to it)  
Changes Take Effect: Immediately  

Specifies the folder, including full path to it, in which an application creates temporary files related to network log output. If you change the option value while the application is running, the change does not affect the currently open network output.

**compatible-output-priority**

Default Value: `false`  
Valid Values:

- `true`  
  The log of the level specified by “Log Output Options” is sent to the specified output.

- `false`  
  The log of the level specified by “Log Output Options” and higher levels is sent to the specified output.

Changes Take Effect: Immediately
Specifies whether the application uses 6.x output logic. For example, you configure the following options in the `log` section for a 6.x application and for a 7.x application:

```
[log]
verbose = all
debug = file1
standard = file2
```

The log file content of a 6.x application is as follows:
- `file1` contains Debug messages only.
- `file2` contains Standard messages only.

The log file content of a 7.x application is as follows:
- `file1` contains Debug, Trace, Interaction, and Standard messages.
- `file2` contains Standard messages only.

If you set `compatible-output-priority` to `true` in the 7.x application, its log file content will be the same as for the 6.x application.

**Warning!** Genesys does not recommend changing the default value of this option unless you have specific reasons to use the 6.x log output logic—that is, to mimic the output priority as implemented in releases 6.x. Setting this option to `true` affects log consistency.

### Log Output Options

To configure log outputs, set log level options (`all`, `alarm`, `standard`, `interaction`, `trace`, and/or `debug`) to the desired types of log output (`stdout`, `stderr`, `network`, `memory`, and/or `[filename]`, for log file output).

You can use:
- One log level option to specify different log outputs.
- One log output type for different log levels.
- Several log output types simultaneously, to log events of the same or different log levels.

You must separate the log output types by a comma when you are configuring more than one output for the same log level. See “Examples” on page 72.

**Warnings!** • If you direct log output to a file on the network drive, an application does not create a snapshot log file (with the extension `.snapshot.log`) in case it terminates abnormally.
- Directing log output to the console (by using the `stdout` or `stderr` settings) can affect application performance. Avoid using these log output settings in a production environment.
**Note:** The log output options are activated according to the setting of the `verbose` configuration option.

**all**
Default Value: No default value
Valid Values (log output types):
- **stdout**: Log events are sent to the Standard output (`stdout`).
- **stderr**: Log events are sent to the Standard error output (`stderr`).
- **network**: Log events are sent to Message Server, which can reside anywhere on the network. Message Server stores the log events in the Log Database.

Setting the `all` log level option to the network output enables an application to send log events of the Standard, Interaction, and Trace levels to Message Server. Debug-level log events are neither sent to Message Server nor stored in the Log Database.

- **memory**: Log events are sent to the memory output on the local disk. This is the safest output in terms of the application performance.
- **[filename]**: Log events are stored in a file with the specified name. If a path is not specified, the file is created in the application’s working directory.

Changes Take Effect: Immediately
Specifies the outputs to which an application sends all log events. The log output types must be separated by a comma when more than one output is configured. For example:

```
all = stdout, logfile
```

**Note:** To ease the troubleshooting process, consider using unique names for log files that different applications generate.

**alarm**
Default Value: No default value
Valid Values (log output types):
- **stdout**: Log events are sent to the Standard output (`stdout`).
- **stderr**: Log events are sent to the Standard error output (`stderr`).
- **network**: Log events are sent to Message Server, which resides anywhere on the network, and Message Server stores the log events in the Log Database.
- **memory**: Log events are sent to the memory output on the local disk. This is the safest output in terms of the application performance.
- **[filename]**: Log events are stored in a file with the specified name. If a path is not specified, the file is created in the application’s working directory.

Changes Take Effect: Immediately
Specifies the outputs to which an application sends the log events of the Alarm level. The log output types must be separated by a comma when more than one output is configured. For example:

```
standard = stderr, network
```

**standard**

Default Value: No default value

Valid Values (log output types):

- **stdout**: Log events are sent to the Standard output (stdout).
- **stderr**: Log events are sent to the Standard error output (stderr).
- **network**: Log events are sent to Message Server, which can reside anywhere on the network. Message Server stores the log events in the Log Database.
- **memory**: Log events are sent to the memory output on the local disk. This is the safest output in terms of the application performance.
- **[filename]**: Log events are stored in a file with the specified name. If a path is not specified, the file is created in the application’s working directory.

Changes Take Effect: Immediately

Specifies the outputs to which an application sends the log events of the **Standard** level. The log output types must be separated by a comma when more than one output is configured. For example:

```
standard = stderr, network
```

**interaction**

Default Value: No default value

Valid Values (log output types):

- **stdout**: Log events are sent to the Standard output (stdout).
- **stderr**: Log events are sent to the Standard error output (stderr).
- **network**: Log events are sent to Message Server, which can reside anywhere on the network. Message Server stores the log events in the Log Database.
- **memory**: Log events are sent to the memory output on the local disk. This is the safest output in terms of the application performance.
- **[filename]**: Log events are stored in a file with the specified name. If a path is not specified, the file is created in the application’s working directory.

Changes Take Effect: Immediately

Specifies the outputs to which an application sends the log events of the **Interaction** level and higher (that is, log events of the **Standard** and **Interaction** levels). The log outputs must be separated by a comma when more than one output is configured. For example:

```
interaction = stderr, network
```
### trace

Default Value: No default value

Valid Values (log output types):

- **stdout**: Log events are sent to the Standard output (stdout).
- **stderr**: Log events are sent to the Standard error output (stderr).
- **network**: Log events are sent to Message Server, which can reside anywhere on the network. Message Server stores the log events in the Log Database.
- **memory**: Log events are sent to the memory output on the local disk. This is the safest output in terms of the application performance.
- **[filename]**: Log events are stored in a file with the specified name. If a path is not specified, the file is created in the application’s working directory.

Changes Take Effect: Immediately

Specifies the outputs to which an application sends the log events of the **Trace** level and higher (that is, log events of the **Standard**, **Interaction**, and **Trace** levels). The log outputs must be separated by a comma when more than one output is configured. For example:

```plaintext
trace = stderr, network
```

### debug

Default Value: No default value

Valid Values (log output types):

- **stdout**: Log events are sent to the Standard output (stdout).
- **stderr**: Log events are sent to the Standard error output (stderr).
- **memory**: Log events are sent to the memory output on the local disk. This is the safest output in terms of the application performance.
- **[filename]**: Log events are stored in a file with the specified name. If a path is not specified, the file is created in the application’s working directory.

Changes Take Effect: Immediately

Specifies the outputs to which an application sends the log events of the **Debug** level and higher (that is, log events of the **Standard**, **Interaction**, **Trace**, and **Debug** levels). The log output types must be separated by a comma when more than one output is configured—for example:

```plaintext
debug = stderr, /usr/local/genesys/logfile
```

**Note:** **Debug**-level log events are never sent to Message Server or stored in the Log Database.
Log File Extensions

You can use the following file extensions to identify log files that an application creates for various types of output:

- *.log—Assigned to log files when you configure output to a log file. For example, if you set standard = confservlog for Configuration Server, it prints log messages into a text file called confservlog.<time_stamp>.log.

- *.qsp—Assigned to temporary (spool) files when you configure output to the network but the network is temporarily unavailable. For example, if you set standard = network for Configuration Server, it prints log messages into a file called confserv.<time_stamp>.qsp during the time the network is not available.

- *.snapshot.log—Assigned to files that contain the output snapshot when you configure output to a log file. The file contains the last log messages that an application generates before it terminates abnormally. For example, if you set standard = confservlog for Configuration Server, it prints the last log message into a file called confserv.<time_stamp>.snapshot.log in case of failure.

**Note:** Provide *.snapshot.log files to Genesys Technical Support when reporting a problem.

- *.memory.log—Assigned to log files that contain the memory output snapshot when you configure output to memory and redirect the most recent memory output to a file. For example, if you set standard = memory and memory = confserv for Configuration Server, it prints the latest memory output to a file called confserv.<time_stamp>.memory.log.

Examples

This section presents examples of a log section that you might configure for an application when that application is operating in production mode and in two lab modes, debugging and troubleshooting.

Production Mode Log Section

```
[log]
verbose = standard
standard = network, logfile
```

With this configuration, an application only generates the log events of the Standard level and sends them to Message Server, and to a file named logfile, which the application creates in its working directory. Genesys recommends that you use this or a similar configuration in a production environment.
Lab Mode Log Section

[log]
verbose = all
all = stdout, /usr/local/genesys/logfile
trace = network

With this configuration, an application generates log events of the Standard, Interaction, Trace, and Debug levels, and sends them to the standard output and to a file named logfile, which the application creates in the /usr/local/genesys/ directory. In addition, the application sends log events of the Standard, Interaction, and Trace levels to Message Server. Use this configuration to test new interaction scenarios in a lab environment.

Failure-Troubleshooting Log Section

[log]
verbose = all
standard = network
all = memory
memory = logfile
memory-storage-size = 32 MB

With this configuration, an application generates log events of the Standard level and sends them to Message Server. It also generates log events of the Standard, Interaction, Trace, and Debug levels, and sends them to the memory output. The most current log is stored to a file named logfile, which the application creates in its working directory. Increased memory storage allows an application to save more of the log information generated before a failure.

Note: If you are running an application on UNIX, and you do not specify any files in which to store the memory output snapshot, a core file that the application produces before terminating contains the most current application log. Provide the application’s core file to Genesys Technical Support when reporting a problem.

Debug Log Options

The options in this section enable you to generate Debug logs containing information about specific operations of an application.
**x-conn-debug-open**
Default Value: 0
Valid Values:
0  Log records are not generated.
1  Log records are generated.
Changes Take Effect: After restart
Generates debug log records about “open connection” operations of the application.

*Warning!* Use this option only when requested by Genesys Technical Support.

**x-conn-debug-select**
Default Value: 0
Valid Values:
0  Log records are not generated.
1  Log records are generated.
Changes Take Effect: After restart
Generates debug log records about “socket select” operations of the application.

*Warning!* Use this option only when requested by Genesys Technical Support.

**x-conn-debug-timers**
Default Value: 0
Valid Values:
0  Log records are not generated.
1  Log records are generated.
Changes Take Effect: After restart
Generates debug log records about the timer creation and deletion operations of the application.

*Warning!* Use this option only when requested by Genesys Technical Support.

**x-conn-debug-write**
Default Value: 0
Valid Values:
0  Log records are not generated.
1  Log records are generated.
Changes Take Effect: After restart
Generates `debug` log records about “write” operations of the application.

**Warning!** Use this option only when requested by Genesys Technical Support.

### x-conn-debug-security
Default Value: 0
Valid Values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Log records are not generated.</td>
</tr>
<tr>
<td>1</td>
<td>Log records are generated.</td>
</tr>
</tbody>
</table>

Changes Take Effect: After restart
Generates `debug` log records about security-related operations, such as Transport Layer Security and security certificates.

**Warning!** Use this option only when requested by Genesys Technical Support.

### x-conn-debug-api
Default Value: 0
Valid Values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Log records are not generated.</td>
</tr>
<tr>
<td>1</td>
<td>Log records are generated.</td>
</tr>
</tbody>
</table>

Changes Take Effect: After restart
Generates `debug` log records about connection library function calls.

**Warning!** Use this option only when requested by Genesys Technical Support.

### x-conn-debug-dns
Default Value: 0
Valid Values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Log records are not generated.</td>
</tr>
<tr>
<td>1</td>
<td>Log records are generated.</td>
</tr>
</tbody>
</table>

Changes Take Effect: After restart
Generates `debug` log records about DNS operations.

**Warning!** Use this option only when requested by Genesys Technical Support.
**x-conn-debug-all**
Default Value: 0
Valid Values:
- 0: Log records are not generated.
- 1: Log records are generated.
Changes Take Effect: After restart
Generates debug log records about open connection, socket select, timer creation and deletion, write, security-related, and DNS operations, and connection library function calls. This option is the same as enabling or disabling all of the previous x-conn-debug-<op type> options.

**Warning!** Use this option only when requested by Genesys Technical Support.

---

**log-extended Section**

This section must be called log-extended.

**level-reassign-<eventID>**
Default Value: Default value of log event <eventID>
Valid Values:
- **alarm**: The log level of log event <eventID> is set to Alarm.
- **standard**: The log level of log event <eventID> is set to Standard.
- **interaction**: The log level of log event <eventID> is set to Interaction.
- **trace**: The log level of log event <eventID> is set to Trace.
- **debug**: The log level of log event <eventID> is set to Debug.
- **none**: Log event <eventID> is not recorded in a log.
Changes Take Effect: Immediately
Specifies a log level for log event <eventID> that is different than its default level, or disables log event <eventID> completely. If no value is specified, the log event retains its default level. This option is useful when you want to customize the log level for selected log events.
These options can be deactivated with the option level-reassign-disable.
Warning! Use caution when making these changes in a production environment.

Depending on the log configuration, changing the log level to a higher priority may cause the log event to be logged more often or to a greater number of outputs. This could affect system performance.

Likewise, changing the log level to a lower priority may cause the log event to be not logged at all, or to be not logged to specific outputs, thereby losing important information. The same applies to any alarms associated with that log event.

In addition to the preceding warning, take note of the following:

- Logs can be customized only by release 7.6 or later applications.
- When the log level of a log event is changed to any level except none, it is subject to the other settings in the [log] section at its new level. If set to none, it is not logged and is therefore not subject to any log configuration.
- Using this feature to change the log level of a log changes only its priority; it does not change how that log is treated by the system. For example, increasing the priority of a log to Alarm level does not mean that an alarm will be associated with it.
- Each application in a High Availability (HA) pair can define its own unique set of log customizations, but the two sets are not synchronized with each other. This can result in different log behavior depending on which application is currently in primary mode.
- This feature is not the same as a similar feature in Universal Routing Server (URS) release 7.2 or later. In this Framework feature, the priority of log events are customized. In the URS feature, the priority of debug messages only are customized. Refer to the Universal Routing Reference Manual for more information about the URS feature.
- You cannot customize any log event that is not in the unified log record format. Log events of the Alarm, Standard, Interaction, and Trace levels feature the same unified log record format.

Example

This is an example of using customized log level settings, subject to the following log configuration:

```
[log]
verbose=interaction
all=stderr
interaction=log_file
standard=network
```
Before the log levels of the log are changed:

- Log event 1020, with default level standard, is output to stderr and log_file, and sent to Message Server.
- Log event 2020, with default level standard, is output to stderr and log_file, and sent to Message Server.
- Log event 3020, with default level trace, is output to stderr.
- Log event 4020, with default level debug, is output to stderr.

Extended log configuration section:

```
[log-extended]
level-reassign-1020=none
level-reassign-2020=interaction
level-reassign-3020=interaction
level-reassign-4020=standard
```

After the log levels are changed:

- Log event 1020 is disabled and not logged.
- Log event 2020 is output to stderr and log_file.
- Log event 3020 is output to stderr and log_file.
- Log event 4020 is output to stderr and log_file, and sent to Message Server.

**level-reassign-disable**

Default Value: false
Valid Values: true, false
Changes Take Effect: Immediately

When this option is set to true, the original (default) log level of all log events in the [log-extended] section are restored. This option is useful when you want to use the default levels, but not delete the customization statements.

---

**log-filter Section**

The log-filter section contains configuration options used to define the default treatment of filtering data in log output. This section contains one configuration option, default-filter-type. Refer to the chapter “Hide Selected Data in Logs” in the Genesys 8.x Security Deployment Guide for complete information about this option.

---

**log-filter-data Section**

The log-filter-data section contains configuration options used to define the treatment of filtering data in log output on a key-by-key basis. This section contains one configuration option in the form of <key name>. Refer to the
security Section

The security section contains configuration options used to specify security elements for your system. In addition to other options that may be required by your application, this section contains the configuration option disable-rbac, which is used to enable or disable Role-Based Access Control for an application. Refer to the chapter “Role-Based Access Control” in the Genesys 8.x Security Deployment Guide for complete information about this option.

sml Section

This section must be called sml.

Options in this section are defined in the Annex of the Application object, as follows:

- in Genesys Administrator—Application object > Options tab > Advanced View (Annex)
- in Configuration Manager—Application object > Properties dialog box > Annex tab

Warning! Use the first three options in this section (heartbeat-period, heartbeat-period-thread-class-<n>, and hangup-restart) with great care, and only with those applications of which support for this functionality has been announced. Failure to use these options properly could result in unexpected behavior, from ignoring the options to an unexpected restart of the application.

heartbeat-period

Default Value: None

Valid Values:

- 0: This method of detecting an unresponsive application is not used by this application.
- 3-604800: Length of timeout, in seconds; equivalent to 3 seconds–7 days.

Changes Take Effect: Immediately

Specifies the maximum amount of time, in seconds, in which heartbeat messages are expected from an application. If Local Control Agent (LCA) does not receive a heartbeat message from the application within this period, it assumes the application is not responding and carries out corrective action.
This option can also be used to specify the maximum heartbeat interval for threads registered with class zero (0). This thread class is reserved for use by the Management Layer only.

If this option is not configured or is set to zero (0), heartbeat detection is not used by this application.

**heartbeat-period-thread-class-<n>**

Default Value: None

Valid Values:

- 0: Value specified by `heartbeat-period` in application is used.
- 3-604800: Length of timeout, in seconds; equivalent to 3 seconds–7 days.

Changes Take Effect: Immediately

Specifies the maximum amount of time, in seconds, in which heartbeat messages are expected from a thread of class `<n>` registered by an application. If a heartbeat message from the thread is not received within this period, the thread is assumed to be not responding, and therefore, the application is unable to provide service.

If this option is not configured or is set to zero (0), but the application has registered one or more threads of class `<n>`, the value specified by the value of `heartbeat-period` for the application will also be applied to these threads.

Refer to application-specific documentation to determine what thread classes, if any, are used.

**hangup-restart**

Default Value: `true`

Valid Values: `true`, `false`

Changes Take Effect: Immediately

If set to `true` (the default), specifies that LCA is to restart the unresponsive application immediately, without any further interaction from Solution Control Server.

If set to `false`, specifies that LCA is only to generate a notification that the application has stopped responding.

**suspending-wait-timeout**

Default Value: 10

Valid Values: 5-600

Changes Take Effect: Immediately

Specifies a timeout (in seconds) after the Stop Graceful command is issued to an application during which the status of the application should change to `Suspending` if the application supports graceful shutdown. If the status of the application does not change to `Suspending` before the timeout expires, it is assumed that the application does not support graceful shutdown, and it is stopped ungracefully.
Use this option if you are unsure whether the Application supports graceful shutdown.

**Note:** Genesys recommends that you do not set this option for any Management Layer component (Configuration Server, Message Server, Solution Control Server, or SNMP Master Agent) or any DB Server. These components by definition do not support graceful shutdown, so this option is not required.

## common Section

This section must be called `common`.

### enable-async-dns

Default Value: `off`

Valid Values:

- `off`: Disables asynchronous processing of DNS requests.
- `on`: Enables asynchronous processing of DNS requests.

Changes Take Effect: Immediately

Enables the asynchronous processing of DNS requests such as, for example, host-name resolution.

**Warnings!** Use this option only when requested by Genesys Technical Support.

### rebind-delay

Default Value: `10`

Valid Values: `0–600`

Changes Take Effect: After restart

Specifies the delay, in seconds, between socket-bind operations that are being executed by the server. Use this option if the server has not been able to successfully occupy a configured port.

**Warning!** Use this option only when requested by Genesys Technical Support.
Related Documentation Resources

The following resources provide additional information that is relevant to this software. Consult these additional resources as necessary.

Solution Documentation

- Documentation for the solution with which you are using LDS (Routing or Reporting).

Genesys

- *Genesys Technical Publications Glossary*, which ships on the Genesys Documentation Library DVD and which provides a comprehensive list of the Genesys and computer-telephony integration (CTI) terminology and acronyms used in this document.

Information about supported hardware and third-party software is available on the Genesys Technical Support website in the following documents:

- *Genesys Supported Operating Environment Reference Manual*
- *Genesys Supported Media Interfaces Reference Manual*

Consult these additional resources as necessary:

- *Genesys Hardware Sizing Guide*, which provides information about Genesys hardware sizing guidelines for Genesys 8.x releases.
- *Genesys Interoperability Guide*, which provides information on the compatibility of Genesys products with various Configuration Layer Environments; Interoperability of Reporting Templates and Solutions; and Gplus Adapters Interoperability.

- *Genesys Licensing Guide*, which introduces you to the concepts, terminology, and procedures relevant to the Genesys licensing system.

For additional system-wide planning tools and information, see the release-specific listings of System Level Documents on the Genesys Technical Support website, accessible from the system level documents by release tab in the Knowledge Base Browse Documents Section.

Genesys product documentation is available on the:

- Genesys Documentation Library DVD, which you can order by e-mail from Genesys Order Management at orderman@genesyslab.com.
Document Conventions

This document uses certain stylistic and typographical conventions—introduced here—that serve as shorthands for particular kinds of information.

Document Version Number

A version number appears at the bottom of the inside front cover of this document. Version numbers change as new information is added to this document. Here is a sample version number:

81fr_us_lds_10-2011_v8.1.001.00

You will need this number when you are talking with Genesys Technical Support about this product.

Screen Captures Used in This Document

Screen captures from the product graphical user interface (GUI), as used in this document, may sometimes contain minor spelling, capitalization, or grammatical errors. The text accompanying and explaining the screen captures corrects such errors except when such a correction would prevent you from installing, configuring, or successfully using the product. For example, if the name of an option contains a usage error, the name would be presented exactly as it appears in the product GUI; the error would not be corrected in any accompanying text.

Type Styles

Table 6 describes and illustrates the type conventions that are used in this document.
